Subject: Submission of Original Research Article

Dear Editors-in-Chief,

We are pleased to submit our original research manuscript entitled:

**“Stateful Selective Maintenance of Two-Level Schwarz Preconditioners
 for Evolving Sparse Linear Systems”**

for consideration for publication as a regular research article in *Computer Methods in Applied Mechanics and Engineering* (CMAME).

Context and Motivation:

In transient continuum mechanics, thermal transport, and multiphysics simulations, numerical time integration generates sequences of large, sparse symmetric positive definite linear algebraic systems $A_t x_t = b_t$. In problems characterized by moving phase-change fronts, localized thermal softening, non-Newtonian boundary layer evolution, or progressive damage, the physical differential operator evolves intensely across a localized sub-region while the vast background remains quasi-static. Traditional parallel domain decomposition methods face an expensive operational dilemma: recomputing all subdomain sparse direct factorizations at every time step prevents Krylov iteration inflation but incurs heavy setup overhead (often 25%–45% of total execution time in three dimensions); conversely, freezing the initial preconditioner statically costs zero setup but triggers severe spectral mismatch and solver divergence.

Core Scientific Contributions:

In this work, we introduce a stateful selective maintenance framework for Two-Level Overlapping Restricted Additive Schwarz (RAS) preconditioners accelerated by sparse direct subdomain solvers (PETSc/MUMPS) and adaptive coarse Galerkin projections. The key contributions include:

1. **Persistent Stateful Architecture:** Rather than rebuilding from scratch or freezing statically, the preconditioner is maintained as a persistent stateful object where symbolic structures are cached and numerical refactorizations are targeted dynamically.
2. **Inexpensive Online Monitoring:** An $\mathcal{O}(n_i)$ diagonal operator-drift proxy senses local perturbations with negligible computational overhead ($< 0.28\%$ of saved setup time), showing strong empirical agreement in subdomain ranking (Pearson $r = 1.0000$, Spearman $\rho_s \in [0.79, 0.98]$ on tested benchmarks).
3. **Mass- α Cumulative-Drift Policy:** Disturbed subdomains are selected via a cumulative staleness metric with aging penalty, balancing local high-frequency correction while the coarse space maintains global error control.
4. **Subdomain Granularity Resolution Effect:** A systematic study across $N_{\text{sub}} \in \{8, 27, 64\}$ quantifies how spatial decomposition resolution enables sharper front isolation, reducing the refactored ratio to 31.8% and eliminating Krylov iteration penalty (47.0 vs. 47.0 iterations).

5. **Certified 3-D Flagship Speedup:** On a flagship 3-D benchmark with 110,592 degrees of freedom (48^3), a 63.9% reduction in preconditioner setup translates into up to a 21.8% reduction in end-to-end simulation runtime ($1.24\times \sim 1.28\times$ net speedup), certified under an independent algebraic residual bound of $\text{RelRes} \leq 3.89 \times 10^{-10} \ll 1.0 \times 10^{-8}$.

Delineation from Contemporary Literature:

We clearly delineate our work from contemporary Krylov subspace recycling (e.g., Hanek, Papež & Šístek, *CMAME* 452 (2026), 118788). While Krylov recycling deflates an invariant operator $Ax_t = b_t$, our framework actively repairs the preconditioner to track a time-evolving operator $A_t x_t = b_t$ ($A_t \neq A_{t-1}$).

Reproducibility Statement:

In accordance with CMAME’s open science and reproducibility standards, the complete source code, benchmark drivers, and verification suites are made publicly available under the MIT license at <https://github.com/Deepsleepinger/JSR> under the official release tag `v1.2-cmame-final`.

We confirm that this manuscript represents original work, has not been published previously, and is not currently under consideration for publication elsewhere. All authors have approved the submission.

Sincerely,

JSR Research Group
